In this study, it was demonstrated that the introduction of Co-Al/Mg-Al hydrotalcite-like compound buffer layers on porous α-Al2O3 substrates enabled effective manipulation of the microstructure of ZIF-7 films so that metal ions located in the inorganic buffer layers were not necessarily identical with those residing in the MOF crystals. Moreover, zinc sources were found to exert a significant influence on the final microstructure of the prepared ZIF-7 films. In addition to ZIF-7, well-intergrown ZIF-8 and HKUST-1 films could also be in situ grown on diverse HTlc buffer layer-modified α-Al2O3 substrates, which convincingly demonstrated the generality of this strategy for the facile preparation of qualified MOF films/membranes.

Introduction

Metal–organic frameworks (MOFs) in the form of thin films have shown unprecedented opportunities and promise in the fields of luminescence,1–3 QCM-based VOC vapor sensing,4–6 optoelectronics,7 gas separation8–11 and catalysis12,13 due to their unique structural flexibility, tailor-made functionalities, large surface areas and adjustable pore apertures.14 Nevertheless, one of the challenging tasks facing MOF film fabrication remains the low-affinity interactions between the chemically inert substrate surface and the MOF crystals, which inevitably gives rise to a low heterogeneous nucleation density.15,16 Therefore, incorporation of additional functional groups into the substrate surface has become indispensable to improve their binding affinity. A variety of organic compounds, including imidazole derivatives,17 PMMA,18 APTES,19 IPTES,20 and PDA,21 have proven effective for substrate activation. In contrast, relatively less attention has been paid to pure inorganic modifiers which, in effect, may show superior performance in inorganic modifiers are identical with those in MOF frameworks. Although some authors tried elucidating this issue in a recent study, the use of conducting substrates and the requirement for electrodeposition of inorganic buffer layers have restricted the potential widespread application.29 Thus, it becomes essential for us to elucidate the principle of inorganic functionalization to bypass such restrictions.

Besides, there is also an increasing demand for facile methods allowing more precise control over the microstructure (like grain size and shape, film thickness and preferred orientation) of MOF films which, however, are mainly based on trial and error and have turned out to be very sophisticated. Taking ZIF-7, a representative of MOF materials, as an example, at present ZIF-7 films with diverse microstructures have to be fabricated by in situ growth, polyethyleneimine (PEI)-assisted seeding,16 microwave-assisted secondary growth,16 benzimidazole covalent functionalization, electrospray deposition10 or the use of sodium formate as a deprotonation agent.17 Comparatively speaking, in situ growth is more preferable for industrial mass production due to its simplicity.31 Therefore, it became highly desirable to enable effective manipulation of microstructures of MOF films via a facile in situ growth method.
Hydrotalcite-like compounds (HTlcs) are a typical representative of anionic clays consisting of positively charged brucite-like layers and charge-compensating anions located in interlayer galleries. Compositional flexibility in both positively charged layers and charge-balancing anions gives rise to a functional diversity. In view of our previous demonstration of high-affinity interactions between HTlc buffer layers and MOF films, herein we further showed that microstructures of ZIF-7 films could be precisely controlled by proper manipulation of structure-related parameters of HTlc buffer layers (schematically shown in Fig. 1). Of particular note is that metal ions present in buffer layers and MOF films are different, which demonstrates convincingly that a much wider range of inorganic compounds are appropriate for a significant enhancement of nucleation and growth of MOF films.

**Experimental**

**Growth of ZIF-7 films on bare α-Al₂O₃ substrates**

0.57 g Zn(NO₃)₂·6H₂O (99.9 wt%, Wako) and 0.31 g benzimidazole (98.0 wt%, TCI) were dissolved in 30 ml DMF (99.5 wt%, nacalai tesque). After vigorous stirring at room temperature for 10 min, a bare α-Al₂O₃ substrate (Fraunhofer Institut, Germany) was placed into a 50 ml Teflon-lined stainless steel vessel, and 35 ml of the precursor solution was poured into the vessel. The vessel was sealed and put into a convection oven with the temperature preheated to 100 °C. After 20 h, the vessel was taken out and cooled to room temperature. Finally, the film was taken out, washed with DMF and dried in air.

**Growth of Co–Al₂O₃ HTlc buffer layers on α-Al₂O₃ substrates**

The precursor solution was prepared by mixing 0.54 g of Co(NO₃)₂·6H₂O (98 wt%, Aldrich), 0.35 g Al(NO₃)₃·9H₂O (98.0 wt%, nacalai tesque) and 1.6 g urea (99.0 wt%, Wako) with 100 ml DDI water. Then a porous α-Al₂O₃ substrate was vertically placed into a 50 ml Teflon-lined stainless steel vessel and 35 ml of the precursor solution was poured into the vessel. The vessel was sealed and put into a convection oven with the temperature preheated to 100 °C. After 20 h, the vessel was taken out and cooled to room temperature. Finally, the substrate was taken out and washed with DDI water.

**Growth of ZIF-7 films on Co–Al₂O₃ HTlc buffer layer-modified α-Al₂O₃ substrates**

This procedure is similar to the synthesis of ZIF-7 films on bare α-Al₂O₃ substrates except that Co–Al₂O₃ HTlc buffer layer-modified α-Al₂O₃ substrates were used.

**Growth of Mg–Al₂O₃ HTlc buffer layers on α-Al₂O₃ substrates**

The precursor solution was prepared by mixing 0.48 g of Mg(NO₃)₂·6H₂O (98 wt%, Aldrich), 0.35 g Al(NO₃)₃·9H₂O and 1.6 g urea with 100 ml DDI water. Then, a porous α-Al₂O₃ substrate was placed into a 50 ml Teflon-lined stainless steel vessel, and 35 ml of the precursor solution was poured into the vessel. The vessel was sealed and put into a convection oven with the temperature preheated to 120 °C. After 20 h, the vessel was taken out and cooled to room temperature. Finally, the substrate was taken out and washed with water.

**Growth of Mg–Al₂O₃ HTlc buffer layers on γ-Al₂O₃ substrates**

This procedure is similar to the synthesis of Mg–Al₂O₃ HTlc on α-Al₂O₃ substrates except that γ-Al₂O₃ substrates are used instead.

**Growth of ZIF-7 films on Mg–Al₂O₃ HTlc buffer layer-modified α-Al₂O₃ substrates**

This procedure is similar to the synthesis of ZIF-7 films on bare α-Al₂O₃ substrates except that Mg–Al₂O₃ HTlc buffer layer-modified α-Al₂O₃ substrates were used instead.

**Growth of ZIF-7 films on Mg–Al₂O₃ HTlc buffer layer-modified γ-Al₂O₃ substrates**

This procedure is similar to the synthesis of ZIF-7 films on bare γ-Al₂O₃ substrates except that Mg–Al₂O₃ HTlc buffer layer-modified γ-Al₂O₃ substrates were used instead.

**Growth of ZIF-7 films on Co–Al₂O₃ HTlc buffer layer-modified α-Al₂O₃ substrates with ZnCl₂ as the zinc source**

0.41 g ZnCl₂ (98.0 wt%, Wako), 0.38 g benzimidazole and 1.02 g diethylamine (99.0 wt%, TCI) were dissolved in 30 ml DMF. After vigorous stirring at room temperature for 10 min, a Co–Al₂O₃ HTlc buffer layer-modified α-Al₂O₃ substrate was vertically placed into a 50 ml Teflon-lined stainless steel vessel, and 30 ml of the precursor solution was poured into the vessel. The vessel was sealed and put into a convection oven with the temperature preheated to 100 °C. After an elapsed time of 20 h, the vessel was taken out and naturally cooled to room temperature in air. Finally, the film was taken out, washed with DMF water and dried in air.

**Growth of ZIF-7 films on Co–Al₂O₃ HTlc buffer layer-modified α-Al₂O₃ substrates with ZnBr₂ as the zinc source**

0.68 g ZnBr₂ (99.9 wt%, Wako), 0.38 g benzimidazole and 1.02 g diethylamine were dissolved in 30 ml DMF. After vigorous stirring at room temperature, a Co–Al₂O₃ HTlc buffer layer-modified α-Al₂O₃ substrate was placed into a 50 ml Teflon-lined stainless steel vessel, and 30 ml of the precursor solution was poured into the vessel. The vessel was sealed and then put into a convection oven with the temperature preheated to 100 °C. After 20 h, the vessel was taken out and cooled to room temperature in air. Finally, the film was taken out, washed with DMF water and dried in air.

**Fig. 1** Schematic illustration of in situ solvothermal synthesis of qualified ZIF-7 films on Co–Al HTlc buffer layer-modified α-Al₂O₃ substrates.
Growth of ZIF-7 films on Co–Al–CO$_3$ HTlc buffer layer-modified α-Al$_2$O$_3$ substrates with ZnI$_2$ as the zinc source

0.96 g ZnI$_2$ (99.0 wt%, nacalai tesque), 0.38 g benzimidazole and 1.02 g diethylamine were dissolved in 30 ml DMF. After vigorous stirring at room temperature, a Co–Al–CO$_3$ HTlc buffer layer-modified α-Al$_2$O$_3$ substrate was placed into a 50 ml Teflon-lined stainless steel vessel, and 30 ml of the precursor solution was poured into the vessel. The vessel was sealed and put into a convection oven with the temperature preheated to 100 °C. After 20 h, the vessel was taken out and cooled to room temperature. Finally, the film was taken out, washed with DMF water and dried in air.

Results and discussion

Effects of Co–Al HTlc buffer layer modification on the microstructure of ZIF-7 films

Initially we tried to prepare ZIF-7 films on bare α-Al$_2$O$_3$ substrates by in situ solvothermal growth with Zn(NO$_3$)$_2$·6H$_2$O as the metal ion source. After the synthesis, large ZIF-7 crystals (grain size ∼10 μm) were readily attached to the substrate (Fig. 2a and b and 3a). Nevertheless, substantial intercrystalline defects remained in the film due to a relatively low nucleation density. To enhance the chemical affinity between the substrates and the ZIF-7 crystals, before solvothermal growth, a Co–Al HTlc buffer layer was introduced to the substrate by in situ hydrothermal growth. As shown in Fig. 2c, the prepared HTlc buffer layer showed a typical plate-like morphology with an average grain size of 4 μm. The mutual distances between adjacent HTlc plates were ∼2 μm (Fig. 2c and d). A high length-to-width ratio of Co–Al HTlc crystals was potentially desirable for substrate modification due to a maximized exposure of surface functional groups as well as minimized mass transfer barrier. The Co/Al ratio was estimated to be 1.28 based on energy-dispersive X-ray spectroscopy (EDXS) measurement (shown in Fig. S1 and S2†). The powder X-ray diffraction (PXRD) pattern further showed distinguishable diffraction peaks at 2θ values of 11.6° and 23.1°, which were coincident with the {003} and {006} crystal planes of the CO$_3^{2-}$ intercalated Co–Al HTlc phase (Fig. 3b; the PXRD pattern is shown in Fig. S3†).36,37

In the next step, ZIF-7 films were in situ synthesized on Co–Al HTlc buffer layer-modified α-Al$_2$O$_3$ substrates. As shown in Fig. 2e, the prepared ZIF-7 film was well intergrown. Moreover, the grain size and film thickness had been significantly reduced to ∼2 μm (Fig. 2e) and 5 μm (Fig. 2f). This can be attributed to the mutual electron donor (benzimidazole N atoms and interlayer OH$^-$/CO$_3^{2-}$ anions)–acceptor (Co$^{2+}$, Al$^{3+}$ and Zn$^{2+}$ ions) interactions between the Co–Al HTlc and the ZIF-7 framework.36,39 The existence of −OH/−CO$_3^{2-}$ functional groups in the Co–Al HTlc buffer layer could be further confirmed by the FT-IR spectra (shown in Fig. S4†).37

Effects of zinc source on the microstructure of ZIF-7 films

Besides buffer layers, zinc sources were found to exert a significant influence on the final microstructure of ZIF-7 films. As shown in Fig. 4, rod-like ZIF-7 crystals were formed and spontaneously attached to Co–Al HTlc buffer layer-modified substrates in case ZnCl$_2$ (Fig. 4a and b)\textsuperscript{40} or ZnBr$_2$ (Fig. 4c and d) were employed as the zinc source. Moreover, it was observed that not only the diameter of the ZIF-7 micro-rods synthesized from ZnBr$_2$ (Fig. 4c) was three times larger than those from ZnCl$_2$ (Fig. 4a), but also they were more closely packed with each other. Cross-sectional SEM images of both prepared ZIF-7 films (Fig. 4b and d) indicated that most ZIF-7 micro-/nano-rods should be vertically aligned on the substrate, which could be interpreted by the “evolution selection” growth mechanism developed by van der Drift in the interpretation of the preferred orientation of a vapor-deposited PbO layer.\textsuperscript{41} Of particular note, the use of ZnI$_2$ as the zinc source unexpectedly resulted in the formation of 50-nm-sized ZIF-7 nanocrystals (shown in Fig. S5\textsuperscript{†}). Morphological differences among ZIF-7 films could be partially interpreted by the hard–soft acid–base (HSAB) theory, in which Cl$^-$/Br$^-$/I$^-$ are classified as hard/intermediate/soft bases, respectively; while Zn$^{2+}$ are defined as intermediate acids.\textsuperscript{40} Since intermediate acids Zn$^{2+}$ tend to form stronger bonds with intermediate bases (Br$^-$), as a result, heterogeneous nucleation of ZIF-7 on Co–Al HTlc-modified substrates is inhibited, which in turn provides enough space for morphology evolvement of ZIF-7 nuclei and ultimately leads to the formation of ZIF-7 films with large grain size and well-developed facets. In contrast, relatively weak interactions between Zn$^{2+}$ (intermediate acids) and Cl$^-$ (hard bases)/I$^-$ (soft bases) give rise to enhanced heterogeneous nucleation and therefore relatively smaller grain size. Our deduction could be further confirmed by a recent study which employed ZnCl$_2$, ZnBr$_2$ and ZnI$_2$ as zinc sources for the preparation of ZIF-8 crystals.\textsuperscript{42} The fact that the largest ZIF-8 nanocrystals were obtained with ZnBr$_2$ as the zinc source was also interpreted based on the HSAB theory.

Effects of HTlc buffer layer morphology on the microstructure of ZIF-7 films

Competent buffer layers are by no means confined to Co–Al HTlc buffer layers. In addition, we further prepared Mg–Al HTlc buffer layers composed of relatively sparsely distributed HTlc plates (Fig. 5a) on which ZIF-7 films with a grain size of 5–10 μm were in situ fabricated (Fig. 5b). Moreover, it was demonstrated that the morphology of the Mg–Al HTlc buffer layers exerted a significant influence on the final morphology of the prepared ZIF-7 films. For easy reference, Mg–Al HTlc buffer layers which consisted of more closely packed HTlc plates (Fig. 5b) were further in situ fabricated on porous γ-Al$_2$O$_3$ substrates. As indicated by the EDXS pattern, the Mg/Al ratio of Mg–Al HTlc buffer layers grown on α-Al$_2$O$_3$ substrates was estimated to be ~2.1 (shown in Fig. S7\textsuperscript{†}). After in situ solvothermal synthesis, well-intergrown ZIF-7 films with a significantly reduced grain size were prepared (grain size ~1 μm, shown in Fig. 5d). This could be reasonably attributed to a remarkably increased number of active nucleation sites on Mg–Al HTlc buffer layer-modified substrates.

Fig. 4 SEM images of ZIF-7 films prepared on Co–Al HTlc buffer layer-modified α-Al$_2$O$_3$ substrates by in situ solvothermal growth with (a and b) ZnCl$_2$, (c and d) ZnBr$_2$ and (e and f) ZnI$_2$ as zinc sources.

Fig. 5 SEM images of (a) Mg–Al HTlc buffer layers prepared on α-Al$_2$O$_3$ substrates, (b) ZIF-7 films prepared on Mg–Al HTlc buffer layer-modified α-Al$_2$O$_3$ substrates by in situ solvothermal growth, (c) Mg–Al HTlc buffer layers prepared on γ-Al$_2$O$_3$ substrates and (d) ZIF-7 films prepared on Mg–Al HTlc buffer layer-modified γ-Al$_2$O$_3$ substrates by in situ solvothermal growth.
All these results demonstrated that it was possible to adjust precisely microstructures of MOF films by judicious manipulation of the structure-related parameters of inorganic buffer layers aside from various solvothermal reaction parameters (like chemical composition of precursors, reaction time and temperature).

It should be emphasized that metal ions present in both HTlc buffer layers and the ZIF-7 framework are distinct, which unambiguously confirms that metal ions residing in inorganic modifiers are not necessarily identical with those in MOF frameworks, and there are no specific criteria for choosing inorganic buffer layers. This implies that in effect, a wide range of inorganic compounds are potentially competent buffer layers for promotion of nucleation and growth of MOF crystals.

**Adhesion strength and reproducibility of ZIF-7 films**

Strong adhesion of MOF crystals to the substrate surface is of vital importance for their practical applications. Herein, ultrasonic testing was carried out to evaluate the adhesion strength of ZIF-7 films. It was found that after 30 minutes of ultrasonic treatment, the prepared ZIF-7 film remained intact and firmly attached to the substrate (shown in Fig. 6). The reinforced mechanical stability of the ZIF-7 film can be attributed to the extra binding strength stemming from the intermediate HTlc network as suggested by previous studies.22,43

The prepared MOF films exhibited high reproducibility in case uniform and continuous HTlc buffer layers could be firmly attached to the substrates. To confirm this assumption, in parallel we prepared six ZIF-7 films on Co–Al HTlc buffer layer-modified α-Al2O3 substrates, and SEM results showed that all ZIF-7 films were well intergrown on a large scale.

**Generality of the developed strategy**

Our approach was confined not only to ZIF-7 film synthesis. With this method, well-intergrown ZIF-8 films could also be fabricated on both Co–Al and Mg–Al HTlc buffer layer-modified α-Al2O3 substrates (shown in Fig. 7). In contrast, ZIF-8 grains were only sparsely distributed on bare α-Al2O3 substrates in the case of direct crystallization as revealed in previous studies. In addition, we further confirmed that continuous HKUST-1 films could be in situ grown on Zn–Al LDH buffer layer-modified γ-Al2O3 substrates (shown in Fig. S8†), therefore demonstrating that this approach could be generalized to significantly promote nucleation and growth of diverse MOF films.

**Conclusions**

In this study we synthesized ZIF-7 films with diverse microstructures (including grain size, crystal morphology, film thickness and preferred orientation) on Co–Al/Mg–Al HTlc buffer layer-modified substrates by in situ solvothermal reaction. It is demonstrated that metal ions present in inorganic buffer layers and MOF films are not necessarily identical. Thus, the scope of inorganic compounds potentially appropriate for surface activation of substrates can be greatly expanded. Moreover, our concept is potentially preferable for mass production of MOF films since the microstructure of MOF films can be easily controlled simply via a facile in situ growth method. This can be realized simply by precisely tuning structure-related parameters of inorganic buffer layers. In addition, the influence of zinc sources on the final microstructures of ZIF-7 films was systematically investigated. We firmly believe that the concept developed here could be potentially beneficial for efficient fabrication of diverse advanced MOF-based hybrid materials.
